

Detection of Waste Sites in Vietnam using Satellite Imagery

Contacts:

Caleb Kruse - caleb@earthrise.media

Maria Edwards - maria@earthrise.media

Summary of Work:

Global Plastic Watch is a tool that detects waste sites in satellite imagery. In this work, the system was run in a high-sensitivity configuration to identify waste sites in Vietnam. Following detection, relevant metadata about the geographic and physical setting is collected. The model was run across all of Vietnam and detected 198 waste sites that could be confirmed using high-resolution satellite imagery. Of these sites, 73 are located within a buffered boundary of ten territories of interest to WWF. For each of the waste site locations, we evaluated the metadata and high-resolution imagery to identify 16 locations that are of highest risk for leakage of waste into rivers and oceans.

Summary of Methods:

We have developed a system that analyzes satellite data to detect aggregations of waste. To our knowledge, no operational monitoring system for municipal solid waste exists. On land, the spectral diversity of waste and land cover makes it challenging to devise spectral indices that can effectively discriminate waste.

This system was developed for the Global Plastic Watch platform, which targets the identification of plastic and municipal waste. With remote detection of waste aggregations, one can measure rather than model waste distributions and monitor waste site development through time, through a globally consistent and comprehensive dataset. The outputs of the tool can be seen at globalplasticwatch.org.

In brief, our waste detection tool is composed of two convolutional neural networks that analyze and combine spectral, spatial, and temporal signals from data collected by the Sentinel-2 satellite. This data has 12 spectral bands, which capture visible and infrared light. The resolution of the data is 10 meters per pixel. This is substantially lower than high-resolution aerial imagery that typically covers 30 cm per pixel, but the Sentinel 2 data is refreshed much more frequently. Having recent multispectral data is essential for waste site identification. A waste site in high-resolution imagery can be seen outlined in red at left, and the same location in the Sentinel-2 data is seen on the right.

The detection system first evaluates each pixel in the region of interest to classify whether it contains waste. For each pixel, the network analyzes all 12 bands of spectral information at two time points to make a determination of whether waste is detected. These pixel predictions are then combined into a heatmap. The pipeline is seen in the following diagram.

The resulting heatmap of predictions for the full region of interest is processed to identify hot spots of waste-positive predictions. Each of these locations is then evaluated by a secondary neural network classifier that incorporates spatial information to make a final determination of whether the region is a waste site.

Full details of the system are detailed in the technical paper, currently under review in [PLOS ONE](#), and available as a [preprint on arXiv.org](#).

Validation of results

Points that are positively classified by both networks are denoted as "candidate sites." To confirm the accuracy of the identifications, these candidates are evaluated by a curator using publicly-available data. Predominantly, validation is done through analysis of very-high resolution satellite data hosted on the Google Earth and Mapbox platforms. This imagery is a composite collected from multiple sensing platforms, but Very-High-Resolution imagery (ranging from under 60 cm and up to 5 m in resolution) is available in most cases. At this

resolution, one can identify characteristic traits that are frequently seen in waste sites. These may include a high frequency texture, pale gray or brown coloration, roads and paths leading to active dumping areas, machinery for moving or dumping waste, or plumes from burning.

Depending on availability, sites may also be verified using other data sources. In Google Street View imagery, reviewers can clearly see the individual waste items as well as the aggregation as a whole. In other cases, data from Planet Planetscope and OpenStreetMap can be used as additional sources of information for site confirmation.

This process has the benefit of limiting the number of false positives. However, it is imperfect. The high-resolution data is frequently older than the data used for detection. Thus, a candidate waste site might be rejected if it is newly created. Additionally, waste aggregations are not always obvious to identify even in the high resolution images. If there is any uncertainty regarding whether a candidate is a waste site, the site is rejected. Additionally, waste aggregations are not always obvious to identify even in the high resolution images. Thus, some sites are labeled as "uncertain" if the validator needs additional information.

Analysis and Results:

Region of Interest and Algorithm Parameters

In this analysis, we evaluated every $10 \times 10\text{m}$ Sentinel-2 pixel captured in all of Vietnam ($3.30 \times 10^5 \text{ km}^2$) at nine time steps between January, 2019 and March, 2021. This produced 39.6 billion predictions at the pixel level and 110 million classifications of patches. To reduce variance, we average the time-step outputs to arrive at a final assessment of the presence of waste.

We ran the system across all of Vietnam, though the client's area of interest falls within the provinces of Thừa Thiên Huế, Quảng Ninh, Quảng Nam, Quảng Bình, Phú Yên, Kiên Giang, Hồ Chí Minh, Hà Tĩnh, Đà Nẵng, Bà Rịa-Vũng Tàu. Waste pollution is frequently transported by rivers, thus a waste site located outside of the study region may still contribute plastic pollution to the target area of interest. Additionally, waste generated in one province may be transported to a site in another. Thus, we buffer the provinces of interest by 0.25° to create the boundaries seen in fig 1.

*Figure 1: Study provinces of interest shown outlined in black.
Buffered regions shown in blue.*

Detection can be run in different sensitivity configurations. The sensitivity parameters balance the algorithm's confidence that a given pixel contains plastic, whether the location has spatial characteristics of a waste site, and the size of a waste site. We ran the system in a high sensitivity configuration. This produces more false positive results, but is also most likely to identify waste.

Site Metadata

For each site that is detected, we create a metadata profile capturing geophysical and environmental parameters. The parameters include soil type information (clay and sand percentage, soil bulk density, and soil great group identity (OpenLandMap), site elevation and slope (SRTM), landform type (Global ALOS Landforms), nearby population (WorldPop), average wind speed (Global Wind Atlas), and distance to nearest water bodies computed from data available through OpenStreetMap. The proximity of a site to a waterway is one of the most important risk factors for the sites

In prior work, we developed risk score metrics for each confirmed municipal waste site. The risk index is a composite of site area (smaller is better), distance to waterway (further is better),

population within 5 km (fewer is better), soil clay percentage (higher is better to avoid groundwater contamination).

The z-score (how far the variable strays from average) is calculated for each variable at every site using the population of all waste sites detected globally. Because all variables other than clay % follow a log normal distribution, the log of the value is taken before computing the z score. Distances to waterways are offset by +10 meters in order to avoid taking a log of 0.

Mathematically, the z-score is expressed as:

$$z_{variable}(x) = \frac{\mu_{variable} - x}{\sigma_{variable}}$$

Where μ represents the mean of the variable, and σ represents the standard deviation of that variable. More simply, the z-score captures whether a parameter is anomalously high or low relative to the values seen in other waste sites worldwide. The z-score values are then multiplied by a scaling factor according to the methodology developed in Widyarsana et al., 2019¹. This is done in order to account for the fact that a waste site that is near to a waterway is a much greater risk than a waste site located near to a populated area. The risk score formula then is computed using the following formula:

$$risk(x) = \frac{69 * z_{\log(water_dist)}(\log(x + 10)) + 41 * z_{clay}(x) - 61 * z_{\log(area)}(\log(x)) - 21 * z_{\log(population)}(\log(x))}{69 + 61 + 41 + 21}$$

For this work, we determined whether a site was of substantial risk manually instead of using a risk score. A manual review is most comprehensive, and also surfaces factors that may not be revealed through a formulaic calculation. Though a manual review of sites would not scale to cover the globe, it was manageable to review the sites detected in this analysis.

Results

Following manual candidate validation using high-resolution imagery, we confirmed the identification of 198 waste sites across the country of Vietnam. 17 industrial waste sites were also found. Industrial waste sites are those containing waste from construction, mining, factories, or other related activities. 16 sites were identified that could not be confirmed as containing waste and could benefit from alternate forms of validation. 31 of the detected waste sites fall within the target provinces, and 73 sites are within the buffered regions of interest (fig 2).

¹ Widyarsana, I. Made Wahyu, et al. "Risk assessment and rehabilitation potential of municipal solid waste landfills in Bali Province, Indonesia." *GEOMATE Journal* 17.63 (2019): 164-171.

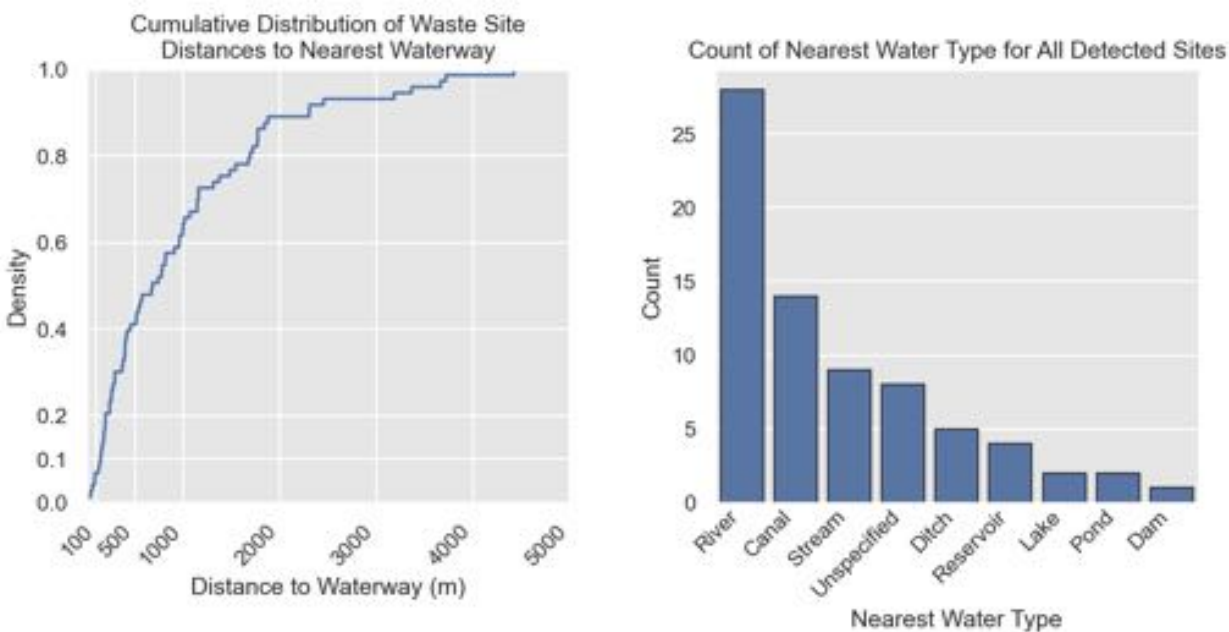

Figure 2. All identified waste sites in Vietnam. Sites within the buffered provinces of interest are shown in yellow.

Of the 73 sites identified within the study area, 17 (23%) were found to be located within 250 meters of a waterway, and five (6.8%) are located within 100 meters of a waterway. The most frequent nearest water type to an identified site is a river (34% of sites). See figure 3.

Cumulative distribution showing the proportion of waste sites as a function distance to the nearest waterway or water body at left. Nearest water type, as listed on OpenStreetMap, is shown at right.

Outputs

All data and assets are located in a public Github repository located at <https://github.com/earthrise-media/vietnam-waste>.

Detected waste sites are shown in figure 2, listed in appendix table 1, and are presented in an interactive web map at <https://earthrise-media.github.io/vietnam-waste/vietnam-v1.0>. The raw data containing the locations and metadata may be downloaded [as a geojson](#) and [as a csv](#).

For each site, we generated a display of high resolution imagery for each site location. Each high-resolution tile is shown with 30cm Mapbox imagery, and links to the corresponding location in Google maps for inspection of surrounding areas. This may be viewed at <https://earthrise-media.github.io/vietnam-waste/vietnam-chips-v1.0>

Sites Assessed to be of High Risk

Based on the evaluation of risk scores, we have made a rough determination of the sites most likely to cause environmental harm within the buffered provinces of interest. These sites are not listed in order of risk.

8f415c80648b89c

Coordinates: 21.117914219535077, 106.4193505210995

Site is flowing directly into a river. Site is active and appears to be expanding.

<https://www.google.com/maps/@21.1181853,106.4189095,309m/data=!3m1!1e3>

8f415c80abadc4b

Coordinates: 21.12580836123202, 106.33025426738622

This site needs on-the-ground validation. It could be construction rubble used to prop up a dam. If confirmed as a waste site, this location seems to be flowing directly into a reservoir. Waste would likely stay within the reservoir.

<https://www.google.com/maps/@21.1260308,106.3299936,309m/data=!3m1!1e3>

8f65a36e6476c28

Coordinates: 10.40231520720859, 104.49435269414005

Site is close to a major river and large. It seems to be managed, and is growing rapidly.

<https://www.google.com/maps/@10.4024023,104.4939334,154m/data=!3m1!1e3>

8f65a3574a16500

Coordinates: 10.092008797442947, 105.02530840706682

There is a lot of waste in this complex. It is near many waterways. No active leakage is seen, but it is of risk. This may also be a private company's waste rather than a municipal waste site.

<https://www.google.com/maps/@10.090538,105.0272239,154m/data=!3m1!1e3>

8f65a3719320908

Coordinates: 10.254714800896219, 104.6164666536214

Site is close to spilling into a small waterway and has spilled in the past. It is uncertain if the waterways lead to the ocean.

<https://www.google.com/maps/@10.2546328,104.6165655,309m/data=!3m1!1e3>

8f65b504d8cc340

Coordinates: 10.393434346993242, 106.78123415682418

This is a very high risk site and is located right on the coast. It seems to be a formal waste site. Site seen to be leaking in March, 2022.

Street View from April 2022 also shows a risky scene.

<https://www.google.com/maps/@10.3936255,106.7812836,154m/data=!3m1!1e3>

8f65b530c792976

Coordinates: 10.37745774018599, 106.64238613527534

Large site with multiple waterways nearby. Site is expanding and seems weakly managed (burning waste, etc).

<https://www.google.com/maps/@10.3772641,106.6423226,154m/data=!3m1!1e3>

8f41656ccd736a5

Coordinates: 16.221814036511528, 107.26118201864537

Site is close to a large water body and is near to leaking.

<https://www.google.com/maps/@16.2215197,107.2611244,306m/data=!3m1!1e3>

8f65a2b4232a459

Coordinates: 9.695618127889684, 105.57014418769243

Site is close to a waterway. And may possibly be actively leaking.

<https://www.google.com/maps/@9.6956223,105.5702147,309m/data=!3m1!1e3>

8f414276d9ae353

Coordinates: 20.81500048583798, 106.75356812807027

There is a risk of leakage into the waterway on the eastern edge. A barrier may have been installed?

<https://www.google.com/maps/@20.8152359,106.7534296,1110m/data=!3m1!1e3>

8f41422a85b5172

Coordinates: 20.82099538679052, 106.59659350831336

There seems to be an informal waste site here. The site is near water and has changed substantially through time.

<https://www.google.com/maps/@20.8209462,106.5964585,154m/data=!3m1!1e3?hl=en-US>

8f41422140ce59c

Coordinates: 20.743888616800696, 106.62665419156276

The site can be seen leaking into a river along the northwestern edge.

<https://www.google.com/maps/@20.7438546,106.6264745,152m/data=!3m1!1e3?hl=en-US>

8f65b5odb691659

Coordinates: 10.661934217441068, 106.85500464482438

Small site, but seen leaking into a waterway.

<https://www.google.com/maps/@10.6619879,106.8549521,154m/data=!3m1!1e3?hl=en-US>

8f65b52328b6984

Coordinates: 10.510675566583732, 106.65076435845413

This site requires confirmation. Its proximity to major river makes for high leakage risk.

<https://www.google.com/maps/@10.5108044,106.6505164,309m/data=!3m1!1e3?hl=en-US>

8f65b529648e2d4

Coordinates: 10.724864307086946, 106.68945574488897

This may only be a construction site. However, the proximity to a river makes for a high risk if confirmed.

<https://www.google.com/maps/@10.7249947,106.6895203,154m/data=!3m1!1e3?hl=en-US>
